MEGESTROL ACETATE TABLETS, USP
Rx only

DESCRIPTION

Megestrol acetate is a synthetic progestogenic and gonadotropin drug. Megestrol acetate is a white, crystalline solid chemically designated as 17(alpha)-acetoxypregna-6,20-dien-3-one-17beta-acetate. It is an oral progestogen that produces effects similar to those of endogenous progesterone.

Megestrol acetate tablets contain the inactive ingredients: acacia, sodium starch glycolate, starch, magnesium stearate, and pregelatinized starch.

CLINICAL PHARMACOLOGY

While the precise mechanism by which megestrol produces its antineoplastic effects against endometrial carcinoma is unknown at the present time, inhibition of plurihormonal gonadotropin production and resultant decrease in estrogen secretion may be factors. There is evidence to suggest a local effect as well, as the marked changes brought about by the direct instillation of progesterone agents into the endometrial cavity. The antineoplastic action of megestrol acetate on carcinoma of the breast is effected by modifying the action of other steroid hormones and by exerting a direct cytotoxic effect on tumor cells. In metastatic breast, hormone receptors are present in some tissues but not others. The receptor mechanism is a cyclic process whereby estrogen produced by the ovaries enters the target cell, forms a complex with cytoplasmic receptor and is transported into the cell nucleus. There it induces gene transcription and leads to the alteration of normal cell functions. Pharmacologic doses of megestrol acetate not only decrease the number of hormone-dependent breast cancer cells but also are capable of modifying and abolishing the stimulatory effects of estrogen on these cells. It has been suggested that progesterone may inhibit in one of two ways: by interfering with either the stability, availability, or turnover of the estrogen receptor complex in its interaction with genes or in conjunction with the progesterin receptor complex, by interacting directly with the genome to turn off specific estrogen-responsive genes.

There are several analytical methods used to estimate megestrol acetate plasma levels, including mass fragmentography, gas chromatography (GC), high pressure liquid chromatography (HPLC), and radioimmunoassay. The plasma levels obtained by HPLC assayed or radioimmunoassay methods are about one-sixth those obtained by the GC method. The plasma levels are dependent not only on the method used, but also on intestinal and hepatic inactivation of the drug, which may be affected by factors such as intestinal tract motility, intestinal bacteria, antibodies administered, body weight, diet, and liver function.

Metabolites account for only 5% to 8% of the administered dose and are considered negligible. The major route of drug elimination in humans is the urine. When radioabeled megestrol acetate was administered to humans in doses of 4 to 90 mg, the urinary excretion within 10 days varied between 83.1% and 94.7% (mean 86.2%). Respiratory excretion of megestrol acetate appeared to be variable. Plasma levels were assayed by a high pressure liquid chromatography (HPLC) procedure. Peak drug levels for the first 40 mg dose ranged from 10 to 56 ng/mL (mean 27.6 ng/mL) and the times to peak concentrations ranged from 1.0 to 3.0 hours (mean 2.2 hours). Plasma elimination half-life ranged from 13.0 to 104.9 hours (mean 34.2 hours). The steady state plasma concentrations for a 40 mg q.i.d. regimen have not been established.

INDICATIONS AND USAGE

Megestrol acetate tablets are indicated for the palliative treatment of advanced carcinoma of the breast or endometrium (i.e., recurrent, inoperable, or metastatic disease). It should not be used in lieu of currently accepted procedures such as surgery, radiation, or chemotherapy.

CONTRAINDICATIONS

History of hypersensitivity to megestrol acetate or any component of the formulation.

WARNINGS

Megestrol acetate may cause fatal harm when administered to a pregnant woman. Fertility and reproduction studies with high doses of megestrol acetate have shown a reversible feminizing effect on some male rat fetuses. There are no adequate and well-controlled studies in pregnant women. If this drug is used during pregnancy, or if the patient becomes pregnant while using this drug, the patient should be apprised of the potential hazard to the fetus. Women of childbearing potential should be advised to avoid becoming pregnant.

The use of megestrol in other types of neoplastic disease is not recommended. (See also PRECAUTIONS, Carcinogenesis, Mutagenesis, Impairment of Fertility section.)

The glucocorticoid activity of megestrol acetate tablets has not been fully evaluated. Clinical cases of new onset diabetes mellitus, exacerbation of pre-existing diabetes mellitus, and overt Cushing’s syndrome have been reported in association with the chronic use of megestrol acetate. Therefore, the possibility of adrenal insufficiency should be considered in any patient receiving or being withdrawn from chronic megestrol acetate therapy, and in patients on therapy. Laboratory evaluation for adrenal insufficiency and consideration of replacement or stress doses of a rapidly acting glucocorticoid are strongly recommended in such patients. Failure to recognize inhibition of pituitary-adrenal axis may result in death. Finally, in patients who are receiving or being withdrawn from chronic megestrol acetate therapy, consideration should be given to the use of empiric therapy with stress doses of a rapidly acting glucocorticoid in conditions of stress or serious intercurrent illness. (e.g., surgery, infection).

PRECAUTIONS

General

Close surveillance is indicated for any patient treated for recurrent or metastatic cancer. Use with caution in patients with a history of thromboembolic disease.

Use in Diabetics

Exacerbation of pre-existing diabetes with increased insulin requirements has been reported in association with the use of megestrol.

Information for the Patients

Patients using megestrol acetate should receive the following instructions:

1. This medication is to be used as directed by the physician.
2. Report any adverse reaction experiences while taking this medication.

Laboratory Tests

Carcinogenesis, Mutagenesis, Impairment of Fertility

Admission of megestrol acetate to female dogs for up to 7 years is associated with an increased incidence of both benign and malignant tumors of the breast. Comparable studies in rats and studies in monkeys are not associated with an increased incidence of tumors.

The relationship of the dog tumors to humans is unknown but should be considered in assessing the benefit-risk ratio when prescribing megestrol acetate and in surveillance of patients on therapy. (See WARNINGS section.)

Pregnancy

Pregnancy Category D. (See WARNINGS section.)

Nursing Mothers

Because of the potential for adverse effects on the newborn, nursing should be discontinued if megestrol is required for treatment of cancer.

Pediatric Use

Safety and effectiveness in pediatric patients have not been established.

Geriatric Use

Insufficient data from clinical studies of megestrol acetate tablets are available for patients 65 years of age and older to determine whether they respond differently than younger patients. Other reported clinical experience has not identified differences in responses between elderly and younger patients. In general, dosage selection for an elderly patient should be cautious, usually starting at the low end of the dosing range, reflecting the greater frequency of decreased hepatic, renal, or cardiac function, and of concomitant disease or other drug therapy.

Megestrol acetate is known to be substantially excreted by the kidney, and the risk of toxic reactions to this drug may be greater in patients with impaired renal function. Because elderly patients are more likely to have decreased renal function, care should be taken in dose selection, and it may be useful to monitor renal function.

ADVERSE REACTIONS

Weight Gain

Weight gain is a frequent side effect of megestrol. This gain has been associated with increased appetite and is not necessarily associated with fluid retention.

Thromboembolic Phenomena

Thromboembolic phenomena including thrombophlebitis and pulmonary embolism have been reported.

Glucocorticoid Effects

(See WARNINGS section.)

Other Adverse Reactions

Heart failure, nausea and vomiting, edema, breakthrough menstrual bleeding, dyspnea, tumor flare (with or without hypocalcemia), hyperglycemia, glucose intolerance, alopecia, hypertension, carpal tunnel syndrome, mood changes, hot flashes, malaise, asthma, lethargy, sweating and rash.

OVERDOSAGE

No serious unexpected side effects have resulted from studies involving megestrol acetate administered in dosages as high as 1600 mg/day. Oral administration of large, single doses of megestrol acetate (5 g/kg) did not produce toxic effects in mice. Megestrol acetate has not been tested for dialyzability; however, due to its low solubility it is postulated that this would not be an effective means of treating overdose.

DOSEAGE AND ADMINISTRATION

Breast cancer: 160 mg/day (40 mg q.i.d.)

Endometrial carcinoma: 40 to 320 mg/day in divided doses.

At least 2 months of continuous treatment is considered an adequate period for determining the efficacy of megestrol acetate.

HOW SUPPLIED

Megestrol acetate tablets, 20 mg, are white, round, flat-faced, beveled-edged, bisected, debossed with “Par 286” on one side. They are supplied in bottles of 100’s (NDC #49884-289-01).

Megestrol acetate tablets, 40 mg, are white, round, flat-faced, beveled-edged, bisected, debossed with “Par 290” on one side. They are supplied in bottles of 100’s (NDC #49884-290-01), 250’s (NDC #49884-295-04) and 500’s (NDC #49884-298-05).
